Outline

- 1 Context
- 2 Isogeometric Analysis
 - B-Splines
- 3 Multigrid
 - Prolongation and Restriction Operators for B-Splines
- 4 GLT: From Cardinal BSplines to the Toeplitz Matrix
- 5 Results: GLT as a Smoother
- 6 Results: GLT + MG
- 7 Mass Matrix on a Circle and a Square
- 8 Conclusions and Future Prospects

- **Aim** : We are interested in devising a robust and optimal solver for the Laplacian operator and the mass matrix.
- **Problem**: Hyperbolic models with small viscosities are in general **strongly nonlinear and coupled and ill-conditioned**.
- **Solutions**: Use algorithm (Physic based preconditioning, semi implicit scheme etc) which allows to **split and reformulate the full system to some simpler systems**.
- **Simple systems**: Laplacian, small advection or vector elliptic operators.
- **Key point**: Operator inversion under control (Convergence, computational cost, robustness, optimality).

Context

- **Linearized Euler Equation:**

$$\begin{cases} \partial_t \mathbf{u} + \mathbf{a} \cdot \nabla \mathbf{u} + c \nabla p & = 0 \\ \partial_t p + \mathbf{a} \cdot \nabla p + c \nabla \cdot \mathbf{u} & = 0 \end{cases} \longrightarrow \begin{cases} \mathbf{u}^{n+1} + \Delta t \mathbf{a} \cdot \nabla \mathbf{u}^{n+1} + c \Delta t \nabla p^{n+1} & = \mathbf{u}^n \\ p^{n+1} + \Delta t \mathbf{a} \cdot \nabla p^{n+1} + c \Delta t \nabla \cdot \mathbf{u}^{n+1} & = p^n \end{cases}$$

- Using splitting scheme with reformulation, we obtain predictor-corrector scheme:

$$\begin{cases} \mathbf{u}^* + \Delta t \mathbf{a} \cdot \nabla \mathbf{u}^* = \mathbf{u}^n \\ p^{n+1} + \Delta t \mathbf{a} \cdot \nabla p^{n+1} - c^2 \Delta t^2 \Delta p^{n+1} = p^n - c \Delta t \nabla \cdot \mathbf{u}^* \\ \mathbf{u}^{n+1} = \mathbf{u}^* - c \Delta t \nabla p^{n+1} \end{cases}$$

- **Conclusion:** when a is small we need to perform mass matrices inversion and stiffness matrix inversion. **Aim: To come up with a Laplacian and mass solver.**
- **Remark:** this approach is extendable to complex systems. Other approaches could give similar outcome.

Isogeometric Analysis

Definition (IgA)

Is a recently developed computational approach that offers the possibility of integrating FEA into conventional CAD design tools.

- Finite Elements Analysis (FEA) models are created from CAD representations.
- Creating FEA models accounts more than 80 % of overall analysis time and is a major engineering bottleneck.
- The geometry is approximated in the FEA mesh
- Use B-Splines as basis functions in the Tokamak context:
 - Adapt geometry to the physics.
 - Using high order polynomial.

B-Splines

B-Splines

To create a family of *B-Splines*, we need a non-decreasing sequence of knots $T = (t_i)_{1 \leq i \leq N+k}$, also called **knot vector**, with $k = p + 1$. Each set of knots $T_j = \{t_j, \dots, t_{j+p}\}$ will generate a *B-spline* N_j .

Definition (B-Spline series)

The j -th B-Spline of order k is defined by the recurrence relation:

$$N_j^k = w_j^k N_j^{k-1} + (1 - w_{j+1}^k) N_{j+1}^{k-1}$$

where,

$$w_j^k(x) = \frac{x - t_j}{t_{j+k-1} - t_j}$$

$$N_j^0(x) = \chi_{[t_j, t_{j+1}[}(x)$$

for $k \geq 1$ and $1 \leq j \leq N$.

Multigrid

Multigrid Idea

Project the system in a subspace, solve the resulting system in this subspace and interpolate the solution in order to improve the previous approximation.

Multigrid Components

The Multigrid combines two iterative methods:

Smoother: a classic iterative method,

Coarse Grid Correction: projection of the error equation, solution of the restricted problem, interpolation.

Multigrid Algorithm

2 Grid Cycle

- 1 **Iterate** on $A_f u = b_f$ to reach u_f (in our case, 5 Gauss-Seidel steps).
- 2 **Restrict** the residual $r_f = b_f - A_f u_f$ to the coarse grid by $r_c = R r_f$
- 3 **Solve** $A_c E_c = r_c$ (or come close to E_c by 5 iterations from $E = 0$).
- 4 **Interpolate** E_c back to $E_f = P E_c$. Add E_f to u_f .
- 5 **Iterate** 5 more times on $A_f u = b_f$ starting from the improved $u_f + E_f$.

Types of cycles:

Prolongation and Restriction Operators for B-Splines

These operators are based on the **knot insertion** algorithm. For the 1D case: one can insert a new knot t , where $t_j \leq t \leq t_{j+1}$.

For this purpose, we use the De Boor's algorithm.

$$\tilde{T} = \{t_1, \dots, t_j, t, t_{j+1}, \dots, t_{N+k}\}$$

$$\alpha_i = \begin{cases} 1, & 1 \leq j \leq j - k + 1 \\ \frac{t - t_j}{t_{i+k-1} - t_j}, & j - k + 2 \leq i \leq j \\ 0, & j + 1 \leq i \end{cases}$$

$$\mathbf{Q}_i = \alpha \mathbf{P}_i + (1 - \alpha_j) \mathbf{P}_{i-1}$$

Prolongation and Restriction Operators Cont'd

This can be written in the matrix form as: $\mathbf{Q} = \mathbf{AP}$. The basis transformation A is called the knot insertion matrix of degree $k-1$ from T to \tilde{T} .

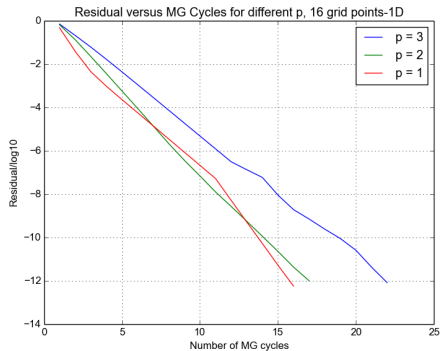

The insertion matrix from T_0 to T_n is simply:

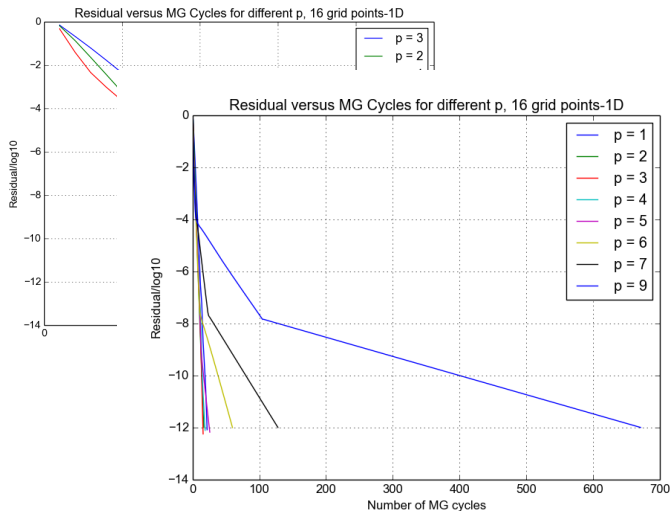

$$A := A_0^n = A_0^1 A_1^2 A_2^3 \dots A_{n-1}^n$$

In 2D, the interpolation operator can be constructed using the Kronecker product.

- 7 Mass Matrix on a Circle and a Square
- 8 Conclusions and Future Prospects

- **PDE:** $Lu = g$ after discretization gives $L_n u_n = g_n$ with $\{L_n\}_n$ is a sequence of discretizations.
- **GLT:** is a generalization of fourier analysis for the discretization of PDEs.
- Application to the **Laplacian operator:** using GLT in the fourier space:

$$L_n \approx M_p D_n$$

Where M_p is homogenous to the mass matrix, and D_n is the FD of the **Laplacian operator** in the fourier space.

- **Low frequency problem:** the eigenvalues of D_n are $(2 - 2\cos(\theta))$, solved via the MG.
- **High frequency problem:** M_p tends to zero when p is large.
- **Idea:** preconditioning by M^{-1} and use exploit kronecker product for the inversion.

GLT: From Cardinal BSplines to the Toeplitz Matrix

Theorem

The symbol m_p is given by

$$m_p(x, \theta) := m_p(\theta) = \phi_{2p+1}(p+1) + 2 \sum_{k=1}^p \phi_{2p+1}(p+1-k) \cos(k\theta)$$

Toeplitz matrix

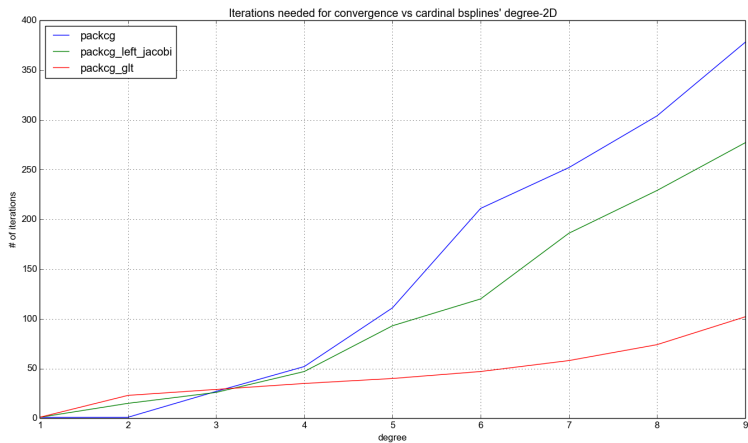

is a real/complex valued $n \times n$ matrix $T_n = (t_{jk})_{j,k=0,\dots,n-1}$, where $t_{jk} = t_{j-k}$, i.e.

$$T_n(f(\theta)) = \begin{pmatrix} t_0 & t_{-1} & t_{-2} & \dots & t_{-(n-1)} \\ t_1 & t_0 & t_{-1} & \dots & \\ t_2 & t_1 & t_0 & \dots & \vdots \\ \vdots & & & \ddots & \\ t_{n-1} & \dots & \dots & \dots & t_0 \end{pmatrix}$$

Conclusions and Future Prospects

Conclusions:

- GLT treats the problem arising from the **high degree component**.
- **GLT + MG** gives a robust and optimal solver for the **Laplacian operator**.
- Can be used also for the **mass matrix**.

Future work:

- Short time:
 - Optimization
 - Apply the **GLT** theory to **vector elliptic operators**; grad div

$$\mu \mathbf{u} - \nabla \nabla \cdot \mathbf{u} = 0$$

Ill-conditioned when $\mu \rightarrow 0$

- Long term: Applying this with time integration schemes for models like **Euler** and **MHD**.
