8 Exaggeration

The meaning of exaggeration is, in general, obvious. However, the principle of *exaggeration* in animation does not mean arbitrarily distorting shapes or objects or making an action more violent or unrealistic. The animator must go to the heart of anything or any idea and develop its essence, understanding the reason for it, so that the audience will also understand it. If a character is sad, make him sadder; if he is bright, make him shine; worried, make him fret; wild, make him frantic.
10. Exaggeration
RIGGING AND SKINNING
Rigging and skinning

- How do we animate complex characters?
  - Skeleton/armature: rigging
  - Skin and flesh: skinning, smooth skinning, muscles, fat, wrinkles
  - Clothing: particle systems, finite elements
Rigging introduction
Rigging a lamp (part 1)
Rigging a lamp (part 2)
Rigging a lamp (part 3)
Rigging a lamp (part 4)
Rigging a human character

Skeleton = “bones”
Geometry = “skin”
Typical Character

- Mechanics of movement must be convincing
- Skin and clothing moves & bends appropriately
- This process of preparing character controls is called rigging
  - Fully rigged character has
    - Skeleton joints, surfaces, deformers, expressions, Set Driven Key, constraints, IK, Blendshapes, etc
Typical Character Rig

Skeleton Joints
Joints are used to create a framework for a character's hierarchy. The rotation of the skeleton joints defines the motion of the character; you can use inverse kinematics for even more control.

Character Controls
Using animation techniques such as Set Driven Key and expressions, you can set up attributes for controlling different parts of a character. For example, a hand joint could have attributes used to control the different finger joints.

Constraints
It is possible to constrain the kinematic controls of a skeleton to objects in your scene or even simple locators. You can then animate the constraint weights to make a character pick something up or grab hold of a fixed object.

Selection Handles
Selection Handles give you quick access to parts of a character's hierarchy that are to be animated. This makes it easier to work with a character after it has been rigged up for animation.

Facial Animation
To animate facial features, you can use deformers such as Blend Shape to create facial poses that can be used for talking and for showing emotion.

Kinematics
To control your skeleton joints, you can choose from Forward or Inverse kinematics. Forward Kinematics allows you to set the joint rotations directly. IK allows you to position IK handles, which rotate the joints.

Bound Surfaces
Surfaces of a character's skin and clothing can be either parented or bound to the skeleton joints to make them move together. Binding places from a surface into clusters that are then associated with particular joints.

Deformers
To help the surfaces bend realistically at joints, deformers such as flexors and influence objects can be used.
Character Resolution

- Use low resolution character that has surfaces “parented” to skeleton
  - Allows interactive animations
  - Switch to full resolution character later
Typical Character Animation Workflow

- Character Design
- Model
- Skeleton Rigging
- Binding
- Animation
- Integration
- Rendering
Animation and interpolation

- Keyframe animation
- How to interpolate motion between key-frames
Articulated motion
Articulated motion
Articulated and rigid motion

- Motion of body part is rigid
  - In the parent’s frame
  - In the word frame
- Rigid motion can be represented as a $3 \times 4$ matrix

\[
M_{b,f} = (S_{b,f} R_{b,f} T_{b,f}) M_{P,f}
\]

\[
S_{b,f} R_{b,f} T_{b,f} = \begin{pmatrix}
S_x R_{11} & S_x R_{12} & S_x R_{13} \\
S_y R_{21} & S_y R_{22} & S_y R_{23} \\
S_z R_{31} & S_z R_{32} & S_z R_{33} \\
T_x & T_y & T_z
\end{pmatrix}
\]
Skinning

- We have a structure of bones, organized as a kinematic tree
- Problem: how do we animate the « skin » of the characters given the motion of their bones?
- Rigid skinning: each body part is modeled as a rigid body
  \[ P(v_i) = T_f P_0(v_i) \] where \( T \) is the bone transformation
Smooth skinning

- Also known as « Skeleton Subspace Deformation »
- Skin vertices move as a result of several body part motions
  \[ P(v_i) = \left( \sum_f w_{if} T_f \right) P_0(v_i) \]
  Normalized weights: \( \sum_f w_{if} = 1 \)
- Vertex weights can be computed automatically
- For example \( w_{if} = 1/d_{if}^2 \)
- Or weights can be drawn by « painting » the skin
Interpolation of matrices

- Transformation matrix $T_f = [SR|t]$ with 12 parameters
- Non independent
- 3 translations, 3 rotations, 3 re-scalings
- Better to control them separately
- Automatic weight computation
- Wang et Philips, Multi-weight enveloping: least-squares approximation techniques for skin animation, SCA 2002
Dual quaternion interpolation

- **Skinning with Dual Quaternions**
Skinning with Dual Quaternions
